

Process Management

Chapter-2 Getting Started..

Process

- In general, a process is a program in execution.
- A Program is not a Process by default. A program is a passive entity, i.e. a file containing a list of instructions stored on disk (secondary memory) (often called an executable file).
- A program becomes a Process when an executable file is loaded into main memory and when it's PCB is created
- A process on the other hand is an Active Entity, which require resources like main memory, CPU time, registers, system buses etc.

Process[Cont'd]

- Even if two processes may be associated with same program, they will be considered as two separate execution sequences and are totally different process.
- For instance, if a user has invoked many copies of web browser program, each copy will be treated as separate process. Even though the text section is same but the data, heap and stack sections can vary.

Process Control Block

- Each process is represented in the operating system by a process control block (PCB) — also called a task control block. PCB simply serves as the repository for any information that may vary from process to process.
- It contains many pieces of information associated with a specific process, including these:

| | |
|--------------------|---------------|
| pointer | process state |
| process number | |
| program counter | |
| registers | |
| memory limits | |
| list of open files | |
| ⋮ | |

Process Control Block[Cont'd]

- Process state: The state may be new, ready, running, waiting, halted, and so on.
- Program counter: The counter indicates the address of the next instruction to be executed for this process.
- CPU registers: The registers vary in number and type, depending on the computer architecture. They include accumulators, index registers, stack pointers, and general-purpose registers, plus any condition-code information. Along with the program counter, this state information must be saved when an interrupt occurs, to allow the process to be continued correctly afterward.

Process Control Block[Cont'd]

- CPU-scheduling information: This information includes a process priority, pointers to scheduling queues, and any other scheduling parameters.
- Memory-management information: This information may include such items as the value of the base and limit registers and the page tables, or the segment tables, depending on the memory system used by the operating system.
- Accounting information: This information includes the amount of CPU and real time used, time limits, account numbers, job or process numbers, and so on.
- I/O status information: This information includes the list of I/O devices allocated to the process, a list of open files, and so on.

A Process consists of following sections:

- **Text section:** also known as Program Code.
- **Stack:** which contains the temporary data (Function Parameters, return addresses and local variables).
- **Data Section:** containing global variables.
- **Heap:** which is memory dynamically allocated during process runtime.

Program Vs. Process

| Program | Process |
|---|--|
| Consists of set of instructions in programming language | It is a sequence of instruction execution |
| It is a static object existing in a file form | It is a dynamic object (i.e. program in execution) |
| Program is loaded into secondary storage device | Process is loaded into main memory |
| The time span is unlimited | Time span is limited |
| It is a passive entity | It is an active entity |

Operations on Process

- The user can perform the following operations on a process in the operating system:
 - Process Creation
 - Process scheduling or dispatching
 - Blocking
 - Preemption
 - Termination

Process Creation

- It's a job of OS to create a process. There are four ways achieving it:
 - For a batch environment a process is created in response to submission of a job.
 - In Interactive environment, a process is created when a new user attempt to log on.
 - The OS can create process to perform functions on the behalf a user program.
 - A number of process can be generated from the main process. For the purpose of modularity or to exploit parallelism a user can create numbers of process.

Process Termination

- A process terminates when it finishes executing its last statement. Its resources are returned to the system, it is purged from any system lists or tables, and its process control block (PCB) is erased. The new process terminates the existing process, usually due to following reasons:
 - **Normal Exit (Voluntary):** Most processes terminate because they have done their job.
 - **Error Exist(Voluntary):** When process discovers a fatal error. For example, a user tries to compile a program that does not exist.
 - **Fatal Error (Involuntary):** An error caused by process due to a bug in program for example, executing an illegal instruction, referring non-existing memory or dividing by zero.
 - **Killed by another Process (Industrial):** A process executes a system call telling the Operating Systems to terminate some other process. In UNIX, this call is kill. In some systems when a process kills all processes it created are killed as well (UNIX does not work this way).

Proces State(2 State Model)

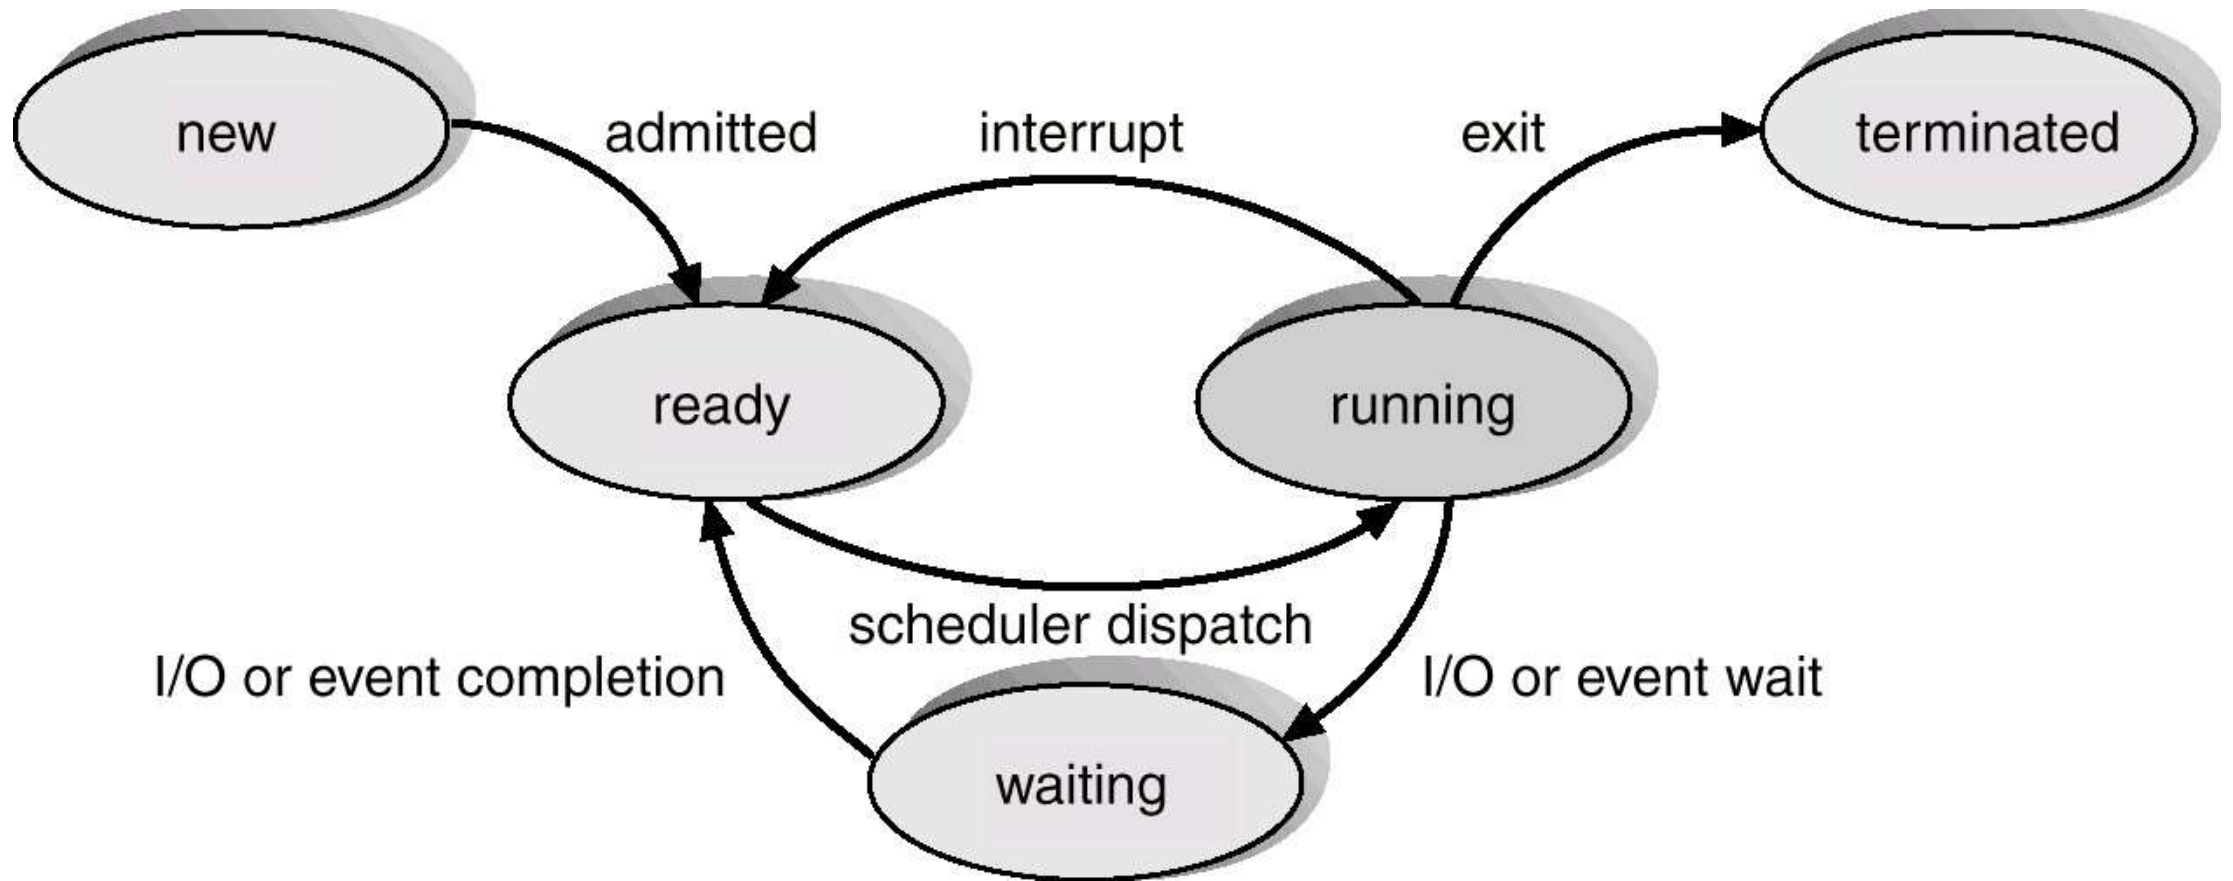

(a) State transition diagram

(b) Queuing diagram

- In this model, we consider two main states of the process. These two states are
 - **State 1:** Process is Running on CPU
 - **State 2:** Process is Not Running on CPU
- **New:** First of all, when a new process is created, then it is in Not Running State. Suppose a new process P2 is created then P2 is in NOT Running State.
- **CPU:** When CPU becomes free, Dispatcher gives control of the CPU to P2 that is in NOT Running state and waiting in a queue.
- **Dispatcher:** Dispatcher is a program that gives control of the CPU to the process selected by the CPU scheduler. Suppose dispatcher allow P2 to execute on CPU.
- **Running:** When dispatcher allows P2 to execute on CPU then P2 starts its execution. Here we can say that P2 is in running state.
- Now, if any process with high priority wants to execute on CPU, Suppose P3 with high priority, then P2 should be the pause or we can say that P2 will be in waiting state and P3 will be in running state.
- Now, when P3 terminates then P2 again allows the dispatcher to execute on CPU

Process State(5 State Model)

1. **New:** A process that has just been created but has not yet been admitted to the pool of executable processes by the OS.
2. **Ready:** Process that is prepared to execute when given the opportunity. That is, they are not waiting on anything except the CPU availability.
3. **Running:** the process that is currently being executed.
4. **Blocked:** A process that cannot execute until some event occurs, such as the completion of an I/O operation.
5. **Exit:** A process that has been released from the pool of executable processes by the OS, either because it is halted or because it is aborted for some reason A process that has been released by OS either after normal termination or after abnormal termination (error).

Scheduling

- The process scheduling is the activity of the process manager that handles the removal of the running process from the CPU and the selection of another process on the basis of a particular strategy.
- The prime aim of the process scheduling system is to keep the CPU busy all the time and to deliver minimum response time for all programs.
- For achieving this, the scheduler must apply appropriate rules for swapping processes IN and out of CPU.

Scheduler

- Schedulers are special system software which handle process scheduling in various ways. Their main task is to select the jobs to be submitted into the system and to decide which process to run.

- **Types of Scheduler**

- Long term scheduler

- Mid - term scheduler

- Short term scheduler

Assignment

- Long Term Scheduler
- Mid-term scheduler
- Short Term Scheduler

Dispatcher

- The dispatcher is the module that gives control of the CPU to the process selected by the short-time scheduler (selects from among the processes that are ready to execute).
- The function involves:
 - Context Switching
 - Switching to user mode
 - Restart the execution of process

Context Switching

- A context switch is the mechanism to store and restore the state of a Process in Process Control block so that a process execution can be resumed from the same point at a later time.
- Using this technique, a context switcher enables multiple processes to share a single CPU.
- Context switching is an essential part of a multitasking operating system features.
- When the scheduler switches the CPU from executing one process to execute another, the state from the current running process is stored into the process control block.
- After this, the state for the process to run next is loaded from its own PCB and used to set the PC, registers, etc. At that point, the second process can start executing.

Process scheduling Types

- In an operating system (OS), a process scheduler performs the important activity of scheduling a process between the ready queues and waiting queue and allocating them to the CPU.
- The OS assigns priority to each process and maintains these queues.
- The scheduler selects the process from the queue and loads it into memory for execution.
- There are two types of process scheduling:
 - Preemptive scheduling
 - Non-preemptive scheduling.

1. Preemptive Scheduling

- The scheduling in which a running process can be interrupted if a high priority process enters the queue and is allocated to the CPU is called preemptive scheduling.
- In this case, the current process switches from the running queue to ready queue and the high priority process utilizes the CPU cycle.

2. Non-Preemptive Scheduling

- The scheduling in which a running process cannot be interrupted by any other process is called non-preemptive scheduling.
- Any other process which enters the queue has to wait until the current process finishes its CPU cycle.

Preemptive Vs. Non- Preemptive Scheduling

| PREEMPTIVE SCHEDULING | NON-PREEMPTIVE SCHEDULING |
|--|--|
| The resources are allocated to a process for a limited time. | Once resources are allocated to a process, the process holds it till it completes its burst time or switches to waiting state. |
| Process can be interrupted in between. | Process cannot be interrupted till it terminates or switches to waiting state. |
| If a high priority process frequently arrives in the ready queue, low priority process may starve. | If a process with long burst time is running CPU, then another process with less CPU burst time may starve. |
| Preemptive scheduling has overheads of scheduling the processes. | Non-preemptive scheduling does not have overheads. |
| Preemptive scheduling is flexible. | Non-preemptive scheduling is rigid. |
| Preemptive scheduling is cost associated. | Non-preemptive scheduling is not cost associative. |

Scheduling Algorithms

- The various scheduling algorithms are as follows:

First Come First Served (FCFS) Scheduling

- It is simplest CPU scheduling algorithm.
- The FCFS scheduling algorithm is non preemptive i.e. once the CPU has been allocated to a process, that process keeps the CPU until it releases the CPU, either by terminating or by requesting I/O.
- In this technique, the process that requests the CPU first is allocated the CPU first.
- When the CPU is free, it is allocated to the process at the head of the queue. The running process is then removed from the queue.
- The average waiting time under this technique is often quite long.

Shortest Job First (SJF) Scheduling

- This technique is associated with the length of the next CPU burst of a process.
- When the CPU is available, it is assigned to the process that has smallest next CPU burst. If the next bursts of two processes are the same, FCFS scheduling is used.
- The SJF algorithm is optimal i.e. it gives the minimum average waiting time for a given set of processes.
- The real difficulty with this algorithm knows the length of next CPU request.

Shortest Remaining Time (SRT) Scheduling

- A preemptive SJF algorithm will preempt the currently executing, whereas a non-preemptive SJF algorithm will allow the currently running process to finish its CPU burst. Preemptive SJF scheduling is also known **Shortest-Remaining-time (SRT) First Scheduling**.
- It is a preemptive version of SJF algorithm where the remaining processing time is considered for assigning CPU to the next process.
- Now we add the concepts of varying arrival times and preemption to the analysis.

Round Robin Scheduling

- Round Robin (RR) scheduling algorithm is designed especially for time sharing systems. It is similar to FCFS scheduling but preemption is added to enable the system to switch between processes. A small unit of time called **time quantum** or **time slice** is defined. A time quantum is generally from 10 to 100 milliseconds in length. The ready queue is treated as a circular queue. The CPU scheduler goes around the ready queue, allocating the CPU to each process for a time interval of up to 1-time quantum.
- The process may have a CPU burst less than 1-time quantum. In this case, the process itself will release the CPU voluntarily. The scheduler will then proceed to the next process in the ready queue. Otherwise, if the CPU burst of the currently running process is longer than 1-time quantum, the timer will go off and will cause an interrupt to the OS. A context switch will be executed, and the process will be put at the tail of the ready queue. The CPU scheduler will then select the next process in the ready queue.
- The average waiting time under the RR policy is often long.

Highest-Response Ratio Next (HRN) Scheduling

- Highest Response Ratio Next (HRRN) scheduling is a non-preemptive discipline, in which the priority of each job is dependent on its estimated run time, and also the amount of time it has spent waiting. Jobs gain higher priority the longer they wait, which prevents indefinite postponement (process starvation).
- It selects a process with the largest ratio of waiting time over service time. This guarantees that a process does not starve due to its requirements.
- In fact, the jobs that have spent a long time waiting compete against those estimated to have short run times.

$$\text{Response Ratio} = (\text{waiting time} + \text{service time}) / \text{service time}$$

Advantages

- Improves upon SJF scheduling
- Still non-preemptive
- Considers how long process has been waiting
- Prevents indefinite postponement

Terminologies

- **Arrival Time (AT):** Time at which process enters a ready state.
- **Burst Time (BT):** Amount of CPU time required by the process to finish its execution.
- **Completion Time (CT):** Time at which process finishes its execution.
- **Turn Around Time (TAT):** Completion Time (CT) – Arrival Time (AT), $WT + BT$
- **Waiting Time (WT):** Turn Around Time (TAT) – Burst Time (BT)
- **Average turnaround time:** $(\sum TAT) / \text{No. of Processes}$
- **Average Waiting Time:** $(\sum WT) / \text{No. of Processes}$

NUMERICALS

1. Schedule the following set of process according to:

- i. FCFS
- ii. SJF
- iii. SRTN
- iv. RR(time quantum = 4 ms)
- v. HRRN

And calculate **average waiting time** and **average turnaround time**.

| Process | Arrival Time(AT) | CPU Time(CT) |
|---------|------------------|--------------|
| A | 0 | 12 |
| B | 2 | 8 |
| C | 5 | 7 |
| D | 10 | 9 |

According to FCFS

Fig: Gantt chart according to FCFS

| Processes | Arrival Time(AT) | CPU Time(CT) |
|-----------|------------------|--------------|
| A | 0 | 12 |
| B | 2 | 8 |
| C | 5 | 7 |
| D | 10 | 9 |

| Process | Arrival Time(AT) | CPU Time/Burst Time | Completion Time(CT) | TAT= CT-AT | WT= TAT-BT |
|---------|------------------|---------------------|---------------------|------------|------------|
| A | 0 | 12 | 12 | 12 | 0 |
| B | 2 | 8 | 20 | 18 | 10 |
| C | 5 | 7 | 27 | 22 | 15 |
| D | 10 | 9 | 36 | 26 | 17 |
| Σ | | | | 78 | 42 |

Average TAT = $\sum \text{TAT} / \text{no. of process} = 78/4 = 19.5 \text{ ms}$

Average WT = $\sum \text{WT} / \text{no. of process} = 42/4 = 10.5 \text{ ms}$

According to SJF

Fig: Ghannt chart according to SJF

| Proces s | Arrival Time(AT) | CPU Time(CT) |
|-------------|---------------------|-----------------|
| A | 0 | 12 |
| B | 2 | 8 |
| C | 5 | 7 |
| D | 10 | 9 |

| Process | Arrival Time(AT) | CPU Time/ Burst Time | Completion Time(CT) | TAT= CT-AT | WT= TAT-BT |
|---------|---------------------|-------------------------|------------------------|------------|------------|
| A | 0 | 12 | 12 | 12 | 0 |
| B | 2 | 8 | 27 | 25 | 17 |
| C | 5 | 7 | 19 | 14 | 7 |
| D | 10 | 9 | 36 | 26 | 17 |
| Σ | | | | 77 | 41 |

Average TAT = $\sum \text{TAT} / \text{no. of process} = 77/4 = 19.25 \text{ ms}$

Average WT = $\sum \text{WT} / \text{no. of process} = 41/4 = 10.25 \text{ ms}$

According to SRTN

Fig: Gantt chart according to SRTN

| Processes | Arrival Time(AT) | CPU Time(CT) |
|-----------|------------------|--------------|
| A | 0 | 12 |
| B | 2 | 8 |
| C | 5 | 7 |
| D | 10 | 9 |

| Process | Arrival Time(AT) | CPU Time/ Burst Time | Completion Time(CT) | TAT= CT-AT | WT= TAT-BT |
|---------|------------------|-------------------------|---------------------|------------|------------|
| A | 0 | 12 | 36 | 36 | 24 |
| B | 2 | 8 | 10 | 8 | 0 |
| C | 5 | 7 | 17 | 12 | 5 |
| D | 10 | 9 | 26 | 16 | 7 |
| Σ | | | | 72 | 36 |

Average TAT = $\sum \text{TAT} / \text{no. of process} = 72/4 = 18 \text{ ms}$

Average WT = $\sum \text{WT} / \text{no. of process} = 36/4 = 9 \text{ ms}$

According to HRRN

After 12ms,

$$(\text{Response Ratio})_B = (WT + ST) / ST = (10 + 8) / 8 = 2.25$$

$$(\text{Response Ratio})_C = (WT + ST) / ST = (7 + 7) / 7 = 2$$

$$(\text{Response Ratio})_D = (WT + ST) / ST = (2 + 9) / 9 = 1.22$$

Here, Process B has highest response ratio.

Hence, Process B will come after process A in Gantt Chart

| Processes | Arrival Time(AT) | CPU Time(CT) |
|-----------|------------------|--------------|
| A | 0 | 12 |
| B | 2 | 8 |
| C | 5 | 7 |
| D | 10 | 9 |

According to HRRN

| Processes | Arrival Time(AT) | CPU Time(CT) |
|-----------|------------------|--------------|
| A | 0 | 12 |
| B | 2 | 8 |
| C | 5 | 7 |
| D | 10 | 9 |

After 20ms,

$$(\text{Response Ratio})_C = (WT + ST) / ST = (15 + 7) / 7 = 3.14$$

$$(\text{Response Ratio})_D = (WT + ST) / ST = (10 + 9) / 9 = 1.88$$

Here, Process C has highest response ratio.

Hence, Process C will come after process B and remaining process D in Gantt Chart.

According to HRRN

| Proces s | Arrival Time(AT) | CPU Time(CT) |
|-------------|---------------------|-----------------|
| A | 0 | 12 |
| B | 2 | 8 |
| C | 5 | 7 |
| D | 10 | 9 |

| Process | Arrival Time(AT) | CPU Time/ Burst Time | Completion Time(CT) | TAT= CT-AT | WT= TAT-BT |
|---------|---------------------|-------------------------|------------------------|------------|------------|
| A | 0 | 12 | 12 | 12 | 0 |
| B | 2 | 8 | 20 | 18 | 10 |
| C | 5 | 7 | 27 | 22 | 15 |
| D | 10 | 9 | 36 | 26 | 17 |
| Σ | | | | 78 | 42 |

Average TAT = $\sum \text{TAT} / \text{no. of process} = 78/4 = 19.5 \text{ ms}$

Average WT = $\sum \text{WT} / \text{no. of process} = 42/4 = 10.5 \text{ ms}$

According to RR (Time quantum =4ms)

- Ready Queue

- Gantt Chart

| Process | Arrival Time(AT) | CPU Time(CT) |
|---------|------------------|--------------|
| A | 0 | 12 |
| B | 2 | 8 |
| C | 5 | 7 |
| D | 10 | 9 |

According to RR

| Processes | Arrival Time(AT) | CPU Time(CT) |
|-----------|------------------|--------------|
| A | 0 | 12 |
| B | 2 | 8 |
| C | 5 | 7 |
| D | 10 | 9 |

■ Ready Queue

■ Gantt Chart

Fig: Gantt chart according to RR

A arrives in ready queue at 0ms.

According to RR

| Processes | Arrival Time(AT) | CPU Time(CT) |
|-----------|------------------|-----------------|

NUMERICALS

3. Schedule the following set of process according to:

- i. FCFS
- ii. SJF
- iii. SRTN
- iv. RR(time quantum = 2 ms)

And calculate **average waiting time** and **average turnaround time**.

| Process | Arrival Time(ms) | CPU Time(ms) |
|---------|------------------|--------------|
| P0 | 0 | 3 |
| P1 | 2 | 6 |
| P2 | 4 | 4 |
| P3 | 6 | 5 |
| P4 | 8 | 2 |

According to FCFS

Fig: Ghannt chart according to FCFS

| Process | Arrival Time(AT) | CPU Time(CT) |
|---------|------------------|--------------|
| P0 | 0 | 3 |
| P1 | 2 | 6 |
| P2 | 4 | 4 |
| P3 | 6 | 5 |
| P4 | 8 | 2 |

| Process | Arrival Time(AT) | CPU Time/ Burst Time | Completion Time(CT) | TAT= CT-AT | WT= TAT-BT |
|---------|------------------|-------------------------|---------------------|------------|------------|
| P0 | 0 | 3 | 3 | 3 | 0 |
| P1 | 2 | 6 | 9 | 7 | 1 |
| P2 | 4 | 4 | 13 | 9 | 5 |
| P3 | 6 | 5 | 18 | 12 | 7 |
| P4 | 8 | 2 | 20 | 12 | 10 |
| Σ | | | | 43 | 23 |

Average TAT = $\sum \text{TAT} / \text{no. of process} = 43/5 = 8.6 \text{ ms}$

Average WT = $\sum \text{WT} / \text{no. of process} = 23/5 = 4.6 \text{ ms}$

According to SJF

Fig: Ghannt chart according to SJF

| Process | Arrival Time(AT) | CPU Time(CT) |
|---------|------------------|--------------|
| P0 | 0 | 3 |
| P1 | 2 | 6 |
| P2 | 4 | 4 |
| P3 | 6 | 5 |
| P4 | 8 | 2 |

| Process | Arrival Time(AT) | CPU Time/ Burst Time | Completion Time(CT) | TAT= CT-AT | WT= TAT-BT |
|---------|------------------|-------------------------|---------------------|------------|------------|
| P0 | 0 | 3 | 3 | 3 | 0 |
| P1 | 2 | 6 | 9 | 7 | 1 |
| P2 | 4 | 4 | 15 | 11 | 7 |
| P3 | 6 | 5 | 20 | 14 | 9 |
| P4 | 8 | 2 | 11 | 3 | 1 |
| Σ | | | | 38 | 18 |

Average TAT = $\Sigma \text{TAT} / \text{no. of process} = 38/5 = 7.6 \text{ ms}$

Average WT = $\Sigma \text{WT} / \text{no. of process} = 18/5 = 3.6 \text{ ms}$

According to SRTN

Fig: Gantt chart according to SRTN

| Process | Arrival Time(AT) | CPU Time(CT) |
|---------|------------------|--------------|
| P0 | 0 | 3 |
| P1 | 2 | 6 |
| P2 | 4 | 4 |
| P3 | 6 | 5 |
| P4 | 8 | 2 |

| Process | Arrival Time(AT) | CPU Time/ Burst Time | Completion Time(CT) | TAT= CT-AT | WT= TAT-BT |
|---------|------------------|-------------------------|---------------------|------------|------------|
| P0 | 0 | 3 | 3 | 3 | 0 |
| P1 | 2 | 6 | 15 | 13 | 7 |
| P2 | 4 | 4 | 8 | 4 | 0 |
| P3 | 6 | 5 | 20 | 14 | 9 |
| P4 | 8 | 2 | 10 | 2 | 0 |
| Σ | | | | 36 | 16 |

NOTE: In SRTN, If 2 processes have same Burst Time, then allocate CPU according to FCFS basics.

Average TAT = $\sum \text{TAT} / \text{no. of process} = 36/5 = 7.2 \text{ ms}$

Average WT = $\sum \text{WT} / \text{no. of process} = 16/5 = 3.2 \text{ ms}$

According to RR (Quantum time = 2ms)

ASSIGNMENT

Completely Fair Scheduler(CFS) used in Linux

- It is the default scheduling process since version 2.6.23.
- Elegant handling of I/O and CPU bound process
- As the name suggests, it fairly or equally divides the CPU time among all the processes.
- Before understanding the CFS let's look at the **Ideal Fair Scheduling (IFS)** of N processes.
- If there are N processes in the ready queue then each process receives $(100/N)\%$ of CPU time according to **IFS**.

Completely Fair Scheduler(CFS) used in Linux

- Let's take four process and their burst time as shown below waiting in the ready queue for the execution.

| Process | Burst Time (in ms) |
|---------|--------------------|
| A | 10 |
| B | 6 |
| C | 14 |
| D | 6 |

Completely Fair Scheduler(CFS) used in Linux

- Take a time quantum of say 4ms. **Initially, there are four processes waiting in the ready queue to be executed**, and according to **Ideal Fair Scheduling**, each process gets equally fair time for its execution (Time quantum/N).
- So $4/4 = 1$, each process gets 1ms to execute in the first quantum. After the completion of six quanta, Process B and D are completely executed, and the remaining are A and C, which have already executed for 6ms, with their remaining times being $A = 4\text{ms}$ and $C = 8\text{ms}$.
- In the seventh quantum of time, A and C will execute ($4/2 = 2\text{ms}$ as there are only two processes remaining). This is Ideal Fair Scheduling, in which each process gets an equal share of the time quantum, no matter what priority it has.

Completely Fair Scheduler(CFS) used in Linux

| Process | Q1 | Q2 | Q3 | Q4 | Q5 | Q6 | Q7 | Q8 | Q9 |
|---------|----|----|----|----|----|----|----|----|----|
| A | 1 | 1 | 1 | 1 | 1 | 1 | 2 | 2 | - |
| B | 1 | 1 | 1 | 1 | 1 | 1 | - | - | - |
| C | 1 | 1 | 1 | 1 | 1 | 1 | 2 | 2 | 4 |
| D | 1 | 1 | 1 | 1 | 1 | 1 | - | - | - |

| Process | Burst Time (in ms) |
|---------|-----------------------|
| A | 10 |
| B | 6 |
| C | 14 |
| D | 6 |

CFS is similar as ideal-based scheduling instead it priorities each process according to their virtual runnable time.

Completely Fair Scheduler(CFS) used in Linux

Idea behind CFS –Each runnable process have a virtual time associated with it in PCB (process control block).

Whenever a context switch happens (or at every scheduling point) then current running process virtual time is increased by,
 $\text{virtualruntime_currprocess} += T$, where T is time for which it is executed recently.

Runtime for the process therefore monotonically increases.

So initially every process have some starting virtual time (you can google how initially virtual run time is calculated).

CFS is quite simple algorithm for the process scheduling and it is implemented using RED BLACK Trees and not queues.

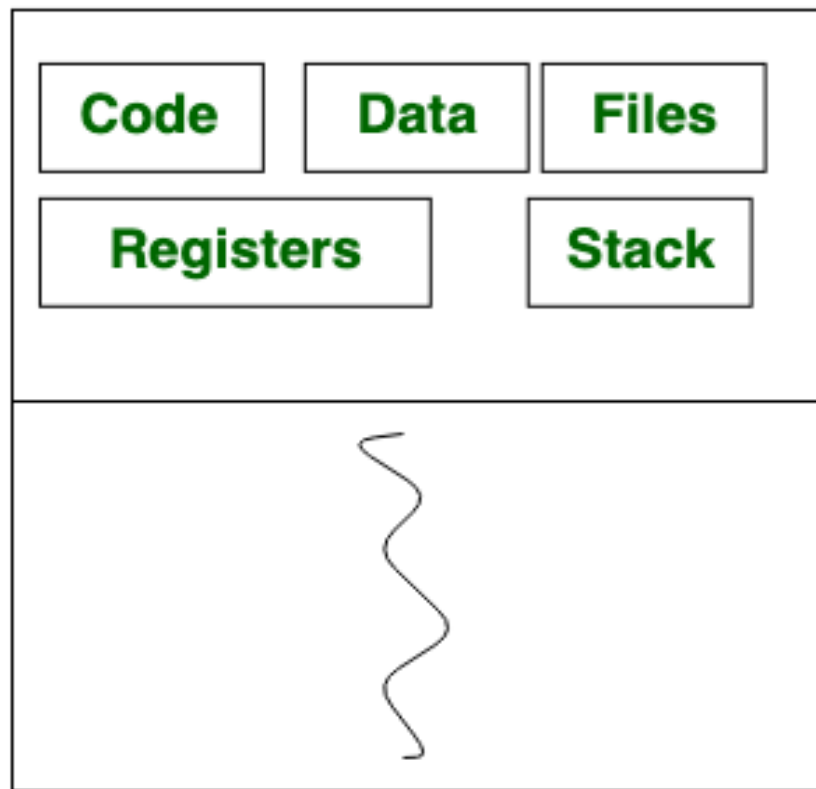

So all the process which are on main memory are inserted into Red Black trees and whenever a new process comes it is inserted into the tree. As we know that Red Black trees are self Balancing binary Search trees.

In C++, we can use maps in STL as they are implemented using red black trees.

Thread

- A thread is a single sequence stream within in a process.
- Because threads have some of the properties of processes, they are sometimes called lightweight processes.
- In many respect, threads are popular way to improve application through parallelism. The CPU switches rapidly back and forth among the threads giving illusion that the threads are running in parallel.
- Like a traditional process i.e., process with one thread, a thread can be in any of several states (Running, Blocked, Ready or terminated).
- A thread consists of a program counter (PC), a register set, and a stack space.
- Threads are not independent of one other like processes. Threads shares address space, program code, global variables, OS resources with other thread.

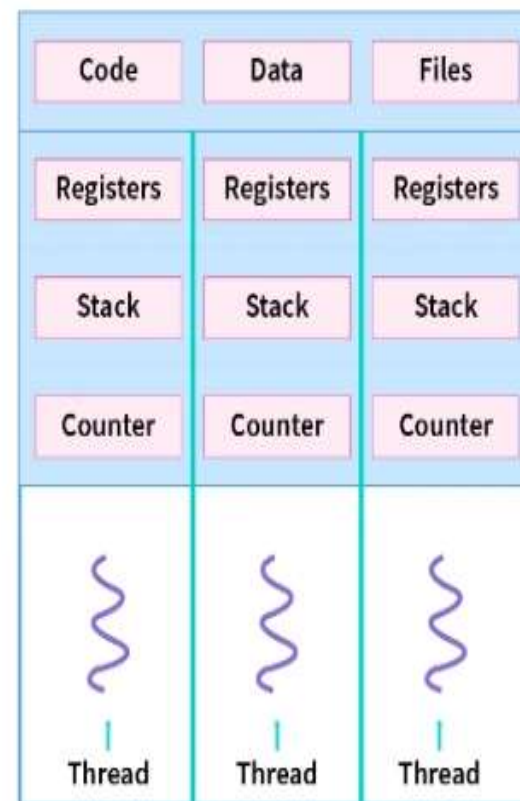

Process

Thread

Single-threaded process

Multithreaded process

Process Vs. Thread

| PROCESS | THREAD |
|--|---|
| Doesn't share memory (loosely coupled). | Shares memories and files (tightly coupled) |
| Creation is time consuming. | Fast |
| Execution is slow. | Fast |
| More time to terminate. | Less time |
| More time to switch between processes. | Less time |
| System calls are required for communication. | Not required |
| More resources are required. | Fewer resources are required |
| Not suitable for parallelism. | Suitable |

Multithreading

- The use of multiple threads in a single program, all running at the same time and performing different tasks is known as multithreading.
- Multithreading is a type of execution model that allows multiple threads to exist within the context of a process such that they execute independently but share their process resources.
- It enables the processing of multiple threads at one time, rather than multiple processes.

Based on functionality, threads are put under 4 categories:

- Single Process, Single Thread (MS-DOS)
- Single Process, Multiple Threads (JAVA Runtime)
- Multiple Process, Single Thread per process (Unix)
- Multiple Process, Multiple Threads (Solaris, Unix)

one process
one thread

one process
multiple threads

multiple processes
one thread per process

multiple processes
multiple threads per process

Types of Thread

- Thread are implemented in following two ways:
 - User Level Threads – User managed threads.
 - Kernel Level Threads – Operating System managed threads acting on kernel, an operating system core.

User Level Threads

- User thread are supported at user level.
- In this case, the thread management kernel is not aware of the existence of threads.
- The thread library contains code for creating and destroying threads, for passing message and data between threads, for scheduling thread execution and for saving and restoring thread contexts.
- In fact, the kernel knows nothing about user-level threads and manages them as if they were single-threaded processes.

Advantages:

- The most obvious advantage of this technique is that a user-level threads package can be implemented on an Operating System that does not support threads.
- User-level thread does not require modification to operating systems.
- **Simple Representation:** Each thread is represented simply by a PC, registers, stack and a small control block, all stored in the user process address space.
- **Simple Management:** This simply means that creating a thread, switching between
- threads and synchronization between threads can all be done without intervention of the kernel.
- **Fast and Efficient:** Thread switching is not much more expensive than a procedure call.

Disadvantages

- There is a lack of coordination between threads and operating system kernel. Therefore, process as whole gets one time slice irrespective of whether process has one thread or 1000 threads within. It is up to each thread to relinquish control to other threads.
- User-level thread requires non-blocking systems call i.e., a multithreaded kernel. Otherwise, entire process will be blocked in the kernel, even if there are runnable threads left in the processes. For example, if one thread causes a page fault, the process blocks.

Kernel-Level Threads

- In this method, the kernel knows about and manages the threads.
- Instead of thread table in each process, the kernel has a thread table that keeps track of all threads in the system.
- Scheduling by the Kernel is done on a thread basis.
- The Kernel performs thread creation, scheduling and management in Kernel space. Kernel threads are generally slower to create and manage than the user threads.

Advantages

- Because kernel has full knowledge of all threads, Scheduler may decide to give more time to a process having large number of threads than process having small number of threads.
- Kernel-level threads are especially good for applications that frequently block.

Disadvantages:

- The kernel-level threads are slow and inefficient. For instance, threads operations are hundreds of times slower than that of user-level threads.
- Since kernel must manage and schedule threads as well as processes. It require a full thread control block (TCB) for each thread to maintain information about threads. As a result, there is significant overhead and increased in kernel complexity.

User Level Vs. Kernel Level Thread

| User-Level Threads | Kernel-Level Thread |
|---|--|
| User-level threads are faster to create and manage. | Kernel-level threads are slower to create and manage. |
| Implementation is by a thread library at the user level. | Operating system supports creation of Kernel threads. |
| User-level thread is generic and can run on any operating system. | Kernel-level thread is specific to the operating system. |
| Multi-threaded applications cannot take advantage of multiprocessing. | Kernel routines themselves can be multithreaded. |

Thread Scheduling
